Utah Health Status Update: Depression

September 2009

Utah Department of Health

Of all mental illnesses, depression is the most common disorder.¹ Approximately 14.8 million adults in the U.S., or 6.7% of the adult population, suffer from major depression each year.² Major depression is the leading cause of disability in the U.S. for ages 15–44.

Depression was selected by the Healthy People 2010 committee in order to monitor progress in mental health treatment among adults. Healthy People 2010 objective 18-9b states "Increase the proportion of adults with recognized depression who receive treatment."

In order to estimate the prevalence of depression in Utah adults, the Patient Health Questionnaire (PHQ-9) was included on the Utah Behavioral Risk Factor Surveillance System (BRFSS) from 2005–2007. The PHQ-9 is a validated screening tool to diagnose clinical depression. The BRFSS is a random-digit-dialed telephone survey of noninstitutionalized persons 18 years of age and older. Survey respondents were classified as having major depression based on a validated algorithm.

Results from the survey indicate that 4.1% of Utah adults, or approximately 75,100 individuals, had major depression. More women (5.1%) were classified as having major depression than men (3.1%). Based on data from 2006, Utah ranked 21st for percentage of adults with major depression compared to the 33 other states that included some variation of the PHQ-9 on the BRFSS that year. Utah's rate (4.2%) was similar to the combined rate (4.2%) of the 34 states. North Dakota had the lowest rate of major depression (2.2%) while West Virginia had the highest rate (7.0%).

The age-adjusted rate of major depression in Utah varied by local health district (LHD). Central Utah LHD had the highest rate of major depression (5.6%) while Summit County LHD had the lowest rate (2.2%). However, neither of these rates is statistically different from the overall state rate of major depression (4.1%). Looking at small areas within LHDs, adults in South Salt Lake had the highest rate of major depression (10.4%) followed by West

Major Depression by Small Area

Figure 1. Percentage of adults reporting current major depression by local health district and small area, Utah, 2005–2007

Orem (8.8%) and West Valley East (8.2%). The lowest rates of major depression were found in the combined West Jordan/Copperton and South Jordan small areas (1.2%), Grand/San Juan County (1.5%) and Sandy Center (1.9%). The South Salt Lake and West Valley East rates were significantly higher than the state rate. The combined West Jordan/Copperton and South Jordan small area and Grand/San Juan County rates were significantly lower than the state rate (see Figure 1).

The prevalence of major depression was higher among adults with selected chronic diseases. People who ever had a stroke had rates of major depression three times higher than those who had never had a stroke (12.0% vs. 3.9%). People who had ever had a heart attack (8.6% vs. 4.0%), had current asthma (8.2% vs. 3.7%), hypertension (7.7% vs.

3.6%), and doctor diagnosed arthritis (7.5% vs. 2.9%) had major depression at more than twice the rate of those without those chronic conditions. Adults with diabetes (6.2% vs. 3.9%) also had higher rates of depression than those not diagnosed (see Figure 2).

A multivariate analysis was performed to determine if certain health behaviors were different for Utah adults who had major depression. The analysis controlled for age, sex, race, education, and employment as individual logistic regression models. Persons who were classified with major depression were 5.4 times more likely to report fair or poor health status, 2.3 times more likely to be current smokers, 1.8 times more likely to report binge drinking, and more than 1.5 times more likely to be obese when compared to people not classified with major depression. They were only about half as likely to engage in the recommended amount of physical activity. Major depression was not related to the consumption of fruits and vegetables (see Figure 3).

Utah has a similar prevalence of major depression when compared to other states using the PHQ-9 analysis, although geographic variation exists within the State. Major depression may be associated with certain chronic conditions, health, and health behaviors. Targeted screening for and treatment of depression should be considered among persons who have had strokes or heart attacks and persons with chronic diseases. Public health efforts towards increased physical activity, smoking cessation, and alcohol addiction should recognize the impact of depression on these behaviors. Timely and appropriate interventions can help improve the quality of life of persons who suffer from this disease.

Breaking News, August 2009

Multiple Births

Natural incidence for twins is 1 in 80 (3%) and for triplets 1 in 8000 (0.2%).* Since 1980 in the U.S. there has been an increase in multiple births by 75% for twins and by 220% for triplets and quadruplets.* The increase in multiple births is attributed to delayed pregnancy, treatment with fertility drugs, and assisted reproductive technology (ART). In the U.S. in the year 2006, ART alone accounted for 1% of all deliveries and 18% of multiple births.*

Gestational age at delivery decreases as fetal number increases. The average gestational age for triplets is 32 weeks and for quadruplets 29 weeks in the U.S. (5 and 8 weeks early, respectively). Babies born early are at risk for multiple long term problems. Prematurity is the most powerful predictor of cerebral palsy and the risk of cerebral palsy is increased among multiple births.*

In summary, although positive achievements in science and technology are undeniable, one must weigh the possibility of undesirable consequences such as extreme prematurity which caries a risk for prolonged hospital stay, long term health problems, neurological deficit, and cognitive impairment.

Community Health Indicators Spotlight, August 2009

Salmonella

Outbreaks of *Salmonella* have become a year-round occurrence; they are being identified and investigated even during the off-peak months for foodborne diseases. This new pattern is due in a large part to improved identification of outbreaks through specialized laboratory techniques that can help public health link distant illnesses together as outbreaks. Over the last 12 months, the Utah Department of Health and local health departments in Utah have partnered with the Centers for Disease

Control and Prevention and other state and local health departments to investigate outbreaks of *Salmonella* that have been linked to turkey products, peanut butter products, and *Salmonella* cultures for school laboratories. Several other outbreaks were investigated for which no source was identified.

During the spring of 2009, public health in Utah investigated an outbreak of *Salmonella* infections linked to *queso fresco*, Mexican-style homemade raw-milk cheese, made privately in people's homes. Public health officials believe the cheese was contaminated from ingredients used to make the *queso fresco*, or from cross-contamination of the cheese. Public health has advised the public to: only use pasteurized milk to make *queso fresco*; keep milk and other ingredients refrigerated; use proper food handling practices to avoid cross contamination; and only buy *queso fresco* from the refrigerated section of the grocery store, not street vendors or door-to-door salesmen.

§ % Change could be due to random variation.

[†] The final Medicaid July old adjustment expendiures have not been posted and are not included in this report. The Medicaid service expenditures reported here are the most current as of the release date of this report.

★ Determination on tier 1 and tier 2 unemployment enhancements and the ARRA rate differentials for the the school districts are still being decided. For these two reasons the total Medicaid Budget amounts are not ready to be released. * Medicaid payments reported under Physician/Osteo Services do not include enhanced physician payments. Notes: Data for notifiable diseases are preliminary and subject to change upon the completion of ongoing disease investigations. Active surveillance for influenza has ended until the 2009 season.
