In Utah, condensation is usually only a problem in the winter because of the cold weather. Condensation happens when the warm air inside touches something cold like a window or cold pipe. Often, a window with condensation on it will look foggy or have little water drops on it.

When trying to control condensation, don’t let warm indoor air touch a cold surface (like a window) long enough that the air gets so cold it forms condensation. Using fans can help keep the air moving. You can also add insulation to cold pipes or windows to help control condensation.

Tips to Control Condensation

- Open a window (even just a crack).
- Move furniture away from the wall (3-6 inches).
- Use fans.
- Use air conditioners.
- Cover cold water pipes with insulation.
